ABSTRACT

AUTOMATICALLY ENABLING EDITING LANGUAGES OF A SOFTWARE PROGRAM

5   A method for enabling editing languages in an application program module is disclosed. The method begins with a determination when the application program boots whether it is the first boot of the application program module. If so, then the user interface (UI) language, Web locale language, help language and install language of the application program module are set to the same language as the operating system user interface (UI) language. If it is not the first boot (or after the languages are set to the operating system UI language), the input locales and operating system scripts are enabled as the editing languages in the application program module. The editing languages for all installed keyboards, IMEs and AIMEs are enabled. Moreover, while the application program module is running, it is determined whether a language is applied within the application program module and, if so, then that language is enabled for editing.
